Management and Technical Services Division

December 5, 2007

Summary:

This is the thirteenth annual report on work-related noise-induced hearing loss (NIHL) in Michigan. Over 1,500 new people with hearing loss known or suspected to be caused by noise at work were reported in 2006 to the Michigan Department of Labor and Economic Growth (MDLEG). Fifty-three percent of the audiograms of the individuals reported with hearing loss had sufficient loss to meet the Occupational Safety and Health Administrative (OSHA) criteria of material hearing loss that significantly affects the ability to understand speech. Fifty-four percent were bothered by tinnitus (ringing, roaring, or buzzing in their ears). Narratives and audiogram on four of the individuals reported are in Appendix I.

Work-related noise-induced hearing loss is affecting mainly men, with an onset at 35-60 years of age. Exposure to noise occurs in many industries but particularly in manufacturing, construction and farming.

Fifty of the 133 (37.59%) companies inspected as part of the surveillance system had no hearing conservation program or a deficient program despite the presence of noise levels above the legal limit (Table 15). Five of these 133 inspections were conducted in the calendar year 2006.

There were 908 health workplace inspections that were conducted by the Michigan Occupational Safety and Health Administration (MIOSHA) in calendar year 2006. Although these inspections were not initiated because of the noise-induced hearing loss surveillance system, 46 of the 908 companies were in violation of some portion of the noise standard. Thirty-four of these 46 companies were cited for having the complete absence of a hearing conservation program. It is important to recognize that the majority of the 908 inspections were in response to a specific complaint or referral. Consequently, the scope of these inspections was primarily limited to the complaint or referral item and noise exposure would not have systemically been addressed unless it was observed to be a serious issue during the course of the inspection.

Noise-induced hearing loss is an insidious condition that may take years to develop to a stage where it affects an individual's ability to communicate at home and in the work place. The frequency of hearing loss increases with the duration of exposure to noise (Figure 8).

The current national system to assess the number of individuals who are developing work-related noise-induced hearing loss has been criticized by the National Academics of Sciences Committee (Board Health Sciences, 2006). Although Michigan is the only state that conducts surveillance for work-related noise-induced hearing loss, Michigan lacks a comprehensive plan to address hearing loss among adults and meet 2010 Health People objectives to reduce hearing loss.

Approximately, 1.4 million adults in Michigan having hearing loss. Work-related NIHL is a significant cause. The 2003 Behavioral Risk Factor Surveillance Survey estimated that 420,000 of the 1.4 million Michigan adults with hearing loss had work-related NIHL. A comprehensive effort to address the burden of this condition in Michigan from both work and non work-related causes is needed.

Background:

Facilities covered by the general industry noise standard (Part 380 Noise Exposure) are required to institute comprehensive hearing conservation programs to prevent noise-induced hearing loss if the 8-hour time-weighted average noise level is at or above 85 decibels. However, the construction industry (as well as transportation, oil and gas well drilling and servicing, agriculture, and mining) are exempted from this comprehensive standard. Project SENSOR (Sentinel Event Notification System for Occupational Risks), the Michigan Department of Labor and Economic Growth's surveillance program for NIHL, provides an estimate of the burden of NIHL in the state, identifies the type of industries where people are developing NIHL and identifies individual facilities that despite legal requirements to have a hearing conservation program lack such a program.

Nationally, one million workers are estimated to have work-related hearing loss, primarily from manufacturing-related exposures to noise (Weeks et al, 1991). Based on data from the National Health Interview Survey, one would expect approximately 86,000 individuals in Michigan to have noise-induced hearing loss related to work place exposures (Ries, 1994). Data from the 2003 Behavioral Risk Factor Surveillance System (BRFSS) provided an even larger estimate; that 420,000 Michigan residents have significant work-related hearing loss.

In 1992, the Michigan Department of Labor and Economic Growth (formerly the Michigan Department of Consumer and Industry Services) with financial assistance from the National Institute for Occupational Safety and Health (NIOSH) initiated a special emphasis program for work-related noise-induced hearing loss (NIHL). Funding assistance from NIOSH ended in September 2000, but was restarted in 2002. The State has continued to maintain work-related NIHL as a priority condition for targeting and intervention during the two-year lapse of federal funding. Direct funding for this project once again lapsed as of June 30, 2006.

The surveillance program is based on Michigan's Occupational Disease Reporting Law, Part 56 of P.A. 368 of 1978, which specifies that any health professional who knows or suspects a patient has a work-related illness must report it to the MDLEG within ten days (Figure 1). The goal of the special emphasis program is to prevent additional work-related hearing loss by inspecting facilities where index individuals with NIHL have worked. The sources used to identify persons with work-related NIHL are: (1) reports from audiologists, otolaryngologists and other health care providers and (2) reports from companies or health care professionals providing services to companies. Both non-company health professionals and those working for industry send reports to the Michigan Department of Labor and Economic Growth.

An individual is considered to have occupational NIHL if a health professional determines the individual: (1) has audiometric findings consistent with noise-induced hearing loss and (2) has a history of exposure to sufficient noise at work to cause hearing loss.

The MIOSHA requirement for recording a standard threshold shift (STS) had been a 10 dB or greater decrease in hearing loss in either ear at an average of 2000, 3000 and 4000 Hz. Since January 1, 2003 the criteria for reporting a STS have changed. Now not only must the individual have the 10 dB STS average at 2000, 3000 and 4000 Hz in either ear but they must also have at

least a 25 dB hearing loss in either ear. For consistency we recommend the 2003 criteria be used for reporting a STS under the Michigan Occupational Disease Reporting Law.

In some cases a hearing health professional will not have access to a baseline audiogram to compare the current audiogram for changes in hearing ability. In response to this, the State advisory committee for work-related NIHL developed some guidelines for reporting hearing loss that do not require a baseline audiogram. The following minimum hearing loss parameters can then be used as a suggested guideline:

A fixed loss (suggested definitions: a 25 dB or greater loss in either ear at an average of: 500, 1000 and 2000 Hz, or 1000, 2,000 and 3000 Hz, or 3000, 4000, and 6000 Hz; or a 15-25 dB or greater loss in either ear at an average of 3000 and 4000 Hz).

Individuals with a standard threshold shift (STS) who are reported by a company medical department or a health professional providing screening services to a company are already enrolled in their company's hearing conservation program (HCP).

Those reported with a hearing loss by a private practice audiology clinic or by an otolaryngologist not part of a company's HCP are followed up by staff working on the NIHL surveillance program to determine if the company where they are or were exposed to noise has a HCP. All individuals with a hearing loss are administered a medical and work history questionnaire, including details on their occupational and recreational exposures to noise.

Beginning in 2003, audiograms have been requested on all individuals reported. These audiograms are used to determine hearing ability. Individuals who have an average hearing loss equal to or greater than 25 decibels at 1000, 2000 and 3000 Hertz are classified as meeting the OSHA criteria of material hearing impairment.

After the patient has been interviewed, a referral for an industrial hygiene investigation is forwarded to the appropriate MIOSHA district if: the individual reports they were exposed to noise and were not provided regular audiometric testing and hearing protection by their employer within the last five years, the facility is in MIOSHA jurisdiction, and the facility has not been inspected within the last five years where noise issues were addressed. Follow-up is typically not performed at companies for which the law does not require the provision of a comprehensive hearing conservation program such as in construction and agriculture. An industrial hygienist conducts monitoring for noise and reviews the completeness and quality of the company's hearing conservation program, if one exists. After the investigation is completed, a report of the results and any recommendations are sent to the company and union (or designated labor representative if the company does not have a union). As requested by the health care providers a copy is also sent to the reporting audiologist or otolaryngologist. If the company is cited for violations of any regulations, they must post the citations at or near the location of the violations for a minimum of three days or until the items have been corrected, whichever is later.

Results:

The results in the thirteenth annual report are presented in the following order: a description of all of the occupational disease reports submitted to the MDLEG for NIHL in the year 2006, results of interviews of individuals with hearing loss identified through Project SENSOR in 2003-2006, a summary of the MIOSHA inspections conducted to follow up individuals with hearing loss, and a summary of the violations of the noise standard that were found during MIOSHA inspections performed from January 1, 2006 to December 31, 2006 that were not conducted as part of project SENSOR.

2006 Work-Related Reports for NIHL

Figure 2 shows the number of reports of hearing loss since 1985. Approximately 12.8% of all occupational disease reports submitted to the Michigan Department of Labor and Economic Growth are for hearing loss. Because of increased awareness of the reporting law by employers and health care providers, there was an increase in the overall number of reports received from 1989 through 2000, and an increase in the number of non-employer based reports received, especially from 1994 through 2001. In 2006, there were 1,572 reports of work-related hearing loss submitted to the Michigan Department of Labor and Economic Growth. Company medical departments or contractors providing audiometric screening for companies submitted 673 of the 1,572 reports in 2006. Non-employer based audiologists, otolaryngologists and occupational medicine physicians submitted the other 899 reports. This is only the second year, the other being 2001 where non-employer based health care professionals submitted more reports than company associated health care providers. Table 1 shows the number of individuals with hearing loss reported by the non-employer based health professionals.

Demographics of Individuals with Hearing Loss

Ninety-one percent (1,433/1,572) of the reports where gender was listed are for men. Although requested, information on race was missing for 1189/1,572 (76%) of the reports. Of the individuals for whom race was known, 79.4% were white, 18.0% were African American, 1.8% were Hispanic and 0.8% were of other descent. These percentages were similar for reports from employer based programs as well as from non-employer based health professionals. The mean age of individuals reported is 58 years, ranging from 18 to 91 years. Individuals reported by companies were generally younger than individuals reported by non-employer based health professionals (average age 52 and 61 years, respectively). Approximately 77% of the individuals reported by employer based programs were between 30 and 59 years of age compared to 44% of non-employer based health professionals in the same age range (Figure 3). Reports by non-employer based health professionals included retired individuals. All reports from employer based programs were of current workers.

Industry

Table 2 and Figure 4 show the number of employees working at the companies where the individuals were exposed to noise. Most of the reports were of individuals who had worked at large companies employing 500 or more employees. Table 3 is a distribution of industry type of

the individuals reported. Most of the reports were for individuals working in manufacturing facilities. This corresponds to companies that are more likely to have hearing conservation programs. However, the non-employer based health professionals reported more individuals from other types of industries, including services (4.8%), transportation and communication services (4.6%), construction (3.1%), and government (3.4%) than the employer based programs. Employer based programs report individuals with NIHL as part of their hearing conservation program (HCP). In contrast, the individuals reported by non-employer based health professionals would not necessarily be working at a company with a HCP.

Individuals with Hearing Loss, Reported by Employer Based Programs and Non-Employer Based Health Professionals in 2003-2006

A total of 5,376 of 5,906 (91%) individuals reported to the surveillance system by employer based programs and non-employer based health professionals since 2003 have been interviewed. The interviews ask about all jobs where a person was exposed to noise. The data on the following pages in the Demographics and Industry sections are from the interviewed individuals reported in 2003-2006.

Demographics of Individuals with Hearing Loss

Ninety-two percent of the interviewed individuals reported in 2003-2006 were men. Of the interviewed individuals reported in 2003-2006 where race was obtained, 82.1% were white, 14.6% were African American, 1.8% were Hispanic, 0.9% were other, and 0.3% were Asian, and 0.3 were American Indian. Race was unknown for 3,187 (59.3%) individuals. Over 83% of the individuals reported were between the ages of 40 to 70 years and includes retirees with hearing loss.

Industry

Table 4 shows all the industries where the individuals with hearing loss were ever exposed to noise. Overall, 85% of the 6,063 types of industries where the 5,376 individuals ever worked were in the manufacturing industry. The 6,063 industries identified are not unique companies; more than one patient may have worked at the same company. Therefore, the company would have been counted more than one time.

Table 5 shows the most recent industries in which the interviewed individuals were exposed to noise and whether the company provided regular hearing tests for their employees. The percentages of companies where the patient reported they did receive regular hearing testing ranged from 0% to 90% within industry types. Seventy-two percent of the most recent companies where the individuals were exposed to noise regularly tested their employees' hearing. The industries that are reported in Table 5 are not unique companies; more than one patient may have worked at the same company. Therefore, the company would have been counted more than once.

Table 6 shows whether individuals reported were provided hearing tests by the number of

employees working in companies where the interviewed individuals were exposed to noise. About half of the workers, in companies with fewer than 100 employees, reported having received regular hearing tests. The industries in Table 6 are not necessarily unique companies; more than one patient may have worked at the same company. Therefore, the company would have been counted more than once.

The interviewed individuals worked in noise for a variety of durations, ranging from less than five years to greater than 35 years. Over 76% were exposed to noise for 20 years or more (Figure 5).

Figure 6 shows the decade of the individuals' first exposure to noise. Some individuals were first exposed to noise many years ago; however, most individuals were first exposed to noise in the 1960's and later (90.7%).

Table 7 shows the decade when the interviewed individuals with hearing loss were most recently exposed to noise by industry. The percentage of individuals at companies with hearing tests increased over time within the industry types that have been required by OSHA (since 1972) to provide such hearing tests. Construction and agriculture industries had the lowest percentages of workers with regular hearing tests; these industries are not required by MIOSHA or OSHA to provide regular hearing tests.

Table 8 shows the decade when the interviewed individuals with hearing loss most recently worked, and whether they were provided with hearing protection (plugs or muffs) by industry type. Over time, the percentage of workers who were provided hearing protection increased in all industries. The percentage of manufacturing workers given hearing protection improved the most of any industry type, with none of the workers given hearing protection in the 1950s and 98% of workers given hearing protection in the 2000s.

Table 9 shows the decade when the interviewed individuals with hearing loss were most recently exposed to noise by company size. Companies with more than 100 employees had higher percentages of workers with regular hearing tests and had greater improvement over time than smaller companies.

Table 10 shows the provision of hearing testing and hearing protection, year began using hearing protection and work injuries by self-reports of how often the individual worked in a noisy environment. Hearing protection was generally not used until the late 1980s. Table 10 also shows self reports of injuries by how often the individual worked in a noisy environment.

Approximately, fifty-four percent of the individuals reported with hearing loss had tinnitus (ringing in the ears) (Table 11). If tinnitus was present then 59% of the time it was daily (Table 11). Table 12 shows the occurrence of non-occupational noise exposures. Target shooting and the use of chain saws were the only two activities where half or more of the respondents indicated they used hearing protection "always or usually." If hearing protection was used, it was generally not used until the 1980s.

Twenty-three percent reported exposure to a chemical or heavy metal that has potential

ototoxicity (Table 13). This information was only collected for jobs where there was also noise exposure.

For the 3,446 individuals for whom we were able to obtain the actual audiogram, 1,835 (53.2%) met the OSHA criteria of material hearing impairment (Figure 7). Race and industry type were very similar for those individuals with material hearing impairment and those with less severe hearing loss (Table 14). There was a significantly greater percent of men with material hearing impairment, 93.7% compared to women with 6.3%. Average age for those with material hearing impairment was 60.6 years, compared to 52.5 years for those with no material hearing impairment (Table 14). Figure 8 shows hearing loss by duration of exposure to noise at work. There is a clear exposure response with increased hearing loss at greater duration. Figure 9 shows that, on the average, hearing in the left ear is worse than the right ear. Individuals who also had exposure to chemical ototoxins were more likely to have material hearing impairment if they had been exposed to any chemical/solvent (58.1% versus 41.9%) ($\chi^2=.000$) as well as for individual chemicals (Table 13).

Inspections

In response to the reports of hearing loss identified through the Project SENSOR Surveillance program, inspections were conducted at 133 companies where the person reported they had never received audiometric testing within the last five years. Of the 133 companies, the inspection showed that 66 (49.6%) were required to have a hearing conservation program (HCP) because they had noise levels at or above 85 dBA. Of those 66 companies, 50 (75.8%) had either no HCP or a deficient HCP. Fifty-five of the 66 companies requiring a HCP were in manufacturing, five were in services, four were in government, one was in the trade industry, and one was in agriculture. Sixty-seven of the 133 companies were not required to have a HCP because noise levels were below 85dBA. Table 15 lists the characteristics of the 133 companies inspected as part of the surveillance efforts.

In addition, three other companies were identified where the person reported they had never received audiometric testing; however, these three companies had been inspected for noise prior to the start of the State's follow-up efforts, between 1987 and 1992. Two of the three had noise levels above 85dBA and no HCP. The other company also had noise levels above 85dBA and a deficient HCP. All three of these companies were in manufacturing.

In the year 2006, there were also industrial hygiene inspections assessing noise exposures that were conducted independently of those referred for inspections based on the patient interviews as part of Project SENSOR. In Michigan, limited scope complaint or referral MIOSHA inspections normally will include review of compliance with the noise standard if the company under investigation clearly has excessive noise levels and employees are observed not wearing hearing protection. During the 908 health inspections conducted in the year 2006, 46 facilities received a citation for a violation of the noise standard. These facilities were generally small. However, 2 (4.3%) of the facilities had more than 250 employees (Table 16). A higher percentage, eleven of the 50 (22%) companies that were inspected in response to hearing loss and received a citation for a violation of the noise standard had more than 250 employees. Thirty-four (54.8%) of the companies were cited for a complete lack of a hearing conservation program despite exposures to

excessive levels of noise. The other companies were cited for violations of sections of the noise standard (Table 17). The manufacture of fabricated metal products, primary metals, industrial and commercial machinery, and transportation equipment were the most common types of companies cited (Table 18).

Table 19 shows the estimates of the number of workers in Michigan industry currently working in conditions with noise levels of 85 decibels or greater.

Case Narratives

The clinical history and the most recent audiogram of four of the individuals who were reported are in Appendix I.

Discussion:

This is the thirteenth annual report of work-related noise-induced hearing loss in Michigan. There were 1,572 reports of hearing loss submitted to the Michigan Department of Labor and Economic Growth in the year 2006. The reports submitted probably represent a substantial underestimate of the total number of individuals with work-related hearing loss. There are approximately 461 audiologists and 148 otolaryngologists in the state. Reports were received in the year 2006 from only two of the 85 estimated group practices in the state, and 28 of the 490 practitioners not known to be associated with a group practice. The number of health care practitioners reporting each year has decreased from previous years (high of 63 in 1994).

The potential number of individuals who should be reported is very likely to be much larger than the number of reports received. In Michigan, we estimate there are currently at minimum 137,100 manufacturing production workers, 25,600 construction workers, 400 oil and gas workers, 27,700 blue collar workers in wholesale and retail trade, and 9,700 workers in service industry environments exposed to daily noise levels of 85 dBA or greater (NIOSH, 1998 and Bureau of Labor Statistics, 2001) (Table 19). Based on 1994 data from the National Health Interview Survey, we would expect approximately 86,000 workers in Michigan to have occupational noise-induced hearing loss (Ries, 1994). A more recent analysis based on the 2003 BRFSS survey estimated 420,000 people in Michigan with occupational noise-induced hearing loss (SENSOR Newsletter, Fall 2004, www.oem.msu.edu). NIOSH has recently received recommendations from a National Academy of Sciences (NAS) Committee on how to improve surveillance for hearing loss. This NAS report noted the many limitations of the current National system to assess this condition (Board Health Sciences, 2006).

The reports submitted are mainly of men between the ages of 40 and 60, who work in large manufacturing companies. Follow-up of reports from employer based programs and non-employer based health professionals show that 72% of noisy companies where the individuals worked had a hearing conservation program when the individual worked there. Over time the numbers of companies that provide regular audiometric testing has increased, especially among manufacturing companies with more than 100 employees. This is not true for smaller

manufacturing companies, and construction companies and the farming industry (Tables 7-9).

The Michigan Department of Labor and Economic Growth has been focusing on hearing loss for 15 years now. In 1993, letters were sent to otolaryngologists, audiologists, speech and hearing clinics, occupational health nurses and mobile van units to educate these groups of health professionals about the reporting law and the importance of reporting known or suspected work-related hearing loss. In 1995, a reminder letter was sent to the state's audiologists and otolaryngologists. Other outreach efforts include presenting mini-seminars at the Michigan Speech-Language-Hearing Association's annual conferences, exhibiting an educational booth about work-related hearing loss at various conferences including the new Michigan Academy of Audiology conference and providing information on the status of the surveillance efforts through various association newsletters. In 1998, we initiated a quarterly newsletter on occupational NIHL that is mailed to the state's approximately 950 audiologists, otolaryngologists, mobile vans and clinics. In 1998, an internet web site that contains the annual reports and newsletters was developed; it can be accessed at: www.oem.msu.edu.

In January 2000, a letter was sent to 719 Michigan hearing health professionals to provide them with a reminder about their obligation to report known or suspected occupational noise-induced hearing loss. In January 2001, a secure server was created to allow for electronic occupational disease report submission via the web site previously mentioned. In 2003, we added the ability to report the audiometric results electronically. Despite these efforts the number of hearing professional reporting work-related noise-induced hearing loss is definitely not increasing, but rather appears to be decreasing. At the same time, the number of reports of hearing loss submitted by non-employer hearing health professionals have not shown a consistent trend, they increased until 1995, decreased in 1996, increased in 1997, decreased in 1998, increased in years 1999-2001, decreased in 2002, increased in 2003, decreased in 2004, and then increased in 2005 and 2006. Further efforts in conjunction with the new licensing regulations for audiologists to encourage reporting are being planned.

In June 2000, MIOSHA initiated an Occupational Noise Exposure Local Emphasis Program (LEP) to comply with their Strategic Plan Goal to reduce NIHL/STS by 15%. Twenty-six categories of manufacturing industries were the focus of this initiative; these were industries known to have large numbers of noise-exposed workers. Inspections were conducted as planned program inspections (i.e. selected because they fell within the targeted industry categories) or as rollover inspections (i.e. the inspection was initiated for a reason other than noise but the facility falls within the LEP's targeted industry categories). At each inspection, the MIOSHA industrial hygienist provided the employer with informational handouts that were appropriate to the operations carried out at that facility. Just like any other MIOSHA enforcement inspection, the company was required to correct any violations of the Michigan noise standard.

The degree of hearing loss among individuals who were reported was significant. Over half met the OSHA criteria for material hearing impairment and would be expected to have difficulty hearing normal speech (Figure 7). Hearing was worse in the left ear as compared to the right (Figure 9) and was worse with increasing duration of exposure (Figure 8). Over half were bothered by tinnitus. Most individuals did not begin to use hearing protection until the late 1980s and most are still not using such protection in noisy activities outside of work. We will continue

to see the adverse effects of this relatively recent initiation of the use of hearing protection. If noise cannot be engineered out of a work place or work process, then more effort is needed to ensure that individuals wear the appropriate hearing protection. This effort must cover work as well as recreational noise. Individuals must also be encouraged to use hearing protection during noisy activities outside of the work place.

Hearing loss is one of the most common medical conditions in the state. The 2003 BRFSS survey estimated there were 1.4 million adults in Michigan with hearing loss. The Nation's public health goals for 2010 include objectives to reduce hearing loss from noise (USHHA, 2000). An effort to develop strategies to increase awareness of the hazards of noise exposure in both occupational and environmental situations and the development of strategies to increase preventive actions is needed.

Ongoing and renewed outreach efforts are needed to increase the number of workers covered by hearing conservation programs, and improve the effectiveness of existing hearing conservation programs. We will continue to encourage health care practitioners to report their patients who have work-related noise-induced hearing loss.

APPENDIX I

Narratives of Four Individuals with Noise-Induced Hearing Loss in 2006

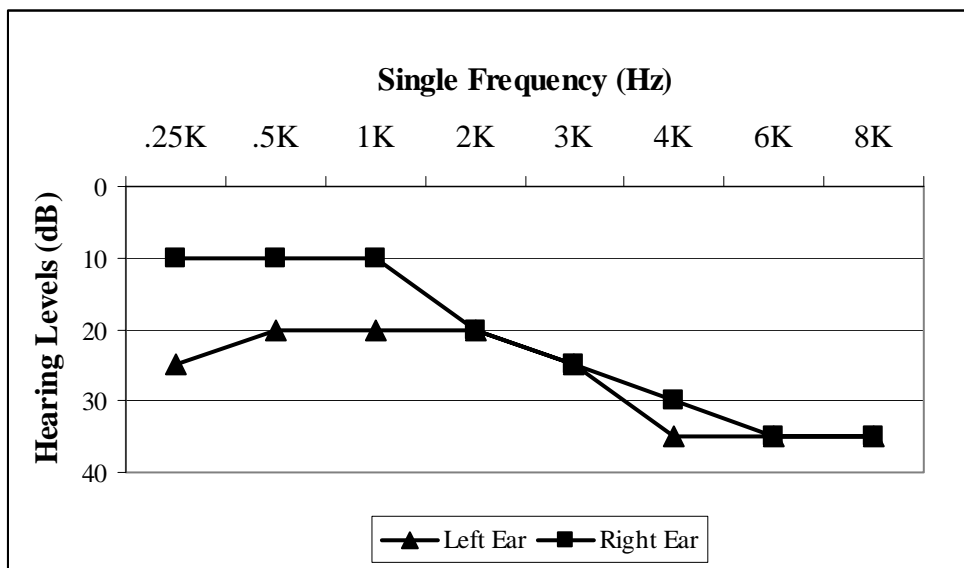

Case 1. A man in his late 40s had hearing loss identified after seeing an audiologist. He had worked in construction for 11 years and reported almost always wearing foam plugs for the last 11 years. He had not been provided hearing testing by any of his employers. He had no other jobs with hearing exposure and had never been in the military. He denied having tinnitus. He was also exposed to noise outside of work. The activities in which he had noise exposure included hunting for 34 years, hobbies with power tools for 30 years, chain saw use for 30 years and lawn work with power tools for 35 years. He always wore hearing protection during these non-work activities, except while doing lawn work with power tools. He had not been told why he had hearing loss. His audiogram is shown in Figure 1.

Case 2. A man in his late 50s had hearing loss identified as part of his company's hearing conservation program. He had several jobs where he was exposed to noise including an asphalt construction company, a chemical company, a bakery, and a university. He stated that he usually wore earmuffs. He had never been in the military. He denied having tinnitus. He was also exposed to noise outside of work. These activities included listening to loud music, motor boating/jet skiing, and lawn work with power tools. He indicated that he never wore hearing protection while engaged in these activities outside of work. He was told that his hearing loss was due to noise in the workplace. His audiogram is shown in Figure 2.

Case 3. A man in his late 30s had hearing loss identified after seeing an audiologist. He worked for multiple different airline companies for the past 13 years. He stated that it was noisy all day every day. He had not been provided hearing testing by any of his employers, however, he was offered hearing protection by his latest employer. He indicated that he almost always wore foam plugs. He had tinnitus daily starting two years ago. He was in the military for four years. He indicated that he was a hunter, practiced target shooting, and lawn work with power tools for the past 15-20 years. He indicated that he always wore hearing protection while engaged in these non-work activities. He had not been told why he had hearing loss. His audiogram is shown in Figure 3.

Case 4. A man in his late 40s had hearing loss identified after seeing an audiologist. He worked for a bakery in the maintenance department for the past 30 years. He began wearing hearing protection twelve years after starting the job. After which he indicated that he almost always wore custom plugs, foam plugs or muffs. He had not been provided hearing testing when he first started working in the bakery, but did start receiving regular testing after working approximately twelve years. He was never in the military. He admitted to having tinnitus daily for the past 11 years. Outside of work he had exposure to noise while listening to loud music and lawn work with power tools. He indicated that for the past two years he always wore hearing protection while doing lawn work. He had not been told why he had hearing loss. His audiogram is shown in Figure 4.
